A BRIEF SURVEY OF HIGGS BUNDLES

UN ESTUDIO CONCISO DE FIBRADOS DE HIGGS

Abstract

Considering a compact Riemann surface of genus greater or equal than two, a Higgs bundle is a pair composed of a holomorphic bundle over the Riemann surface, joint with an auxiliar vector field, so-called Higgs field. This theory started around thirty years ago, with Hitchin's work, when he reduced the self-duality equations from dimension four to dimension two, and so, studied those equations over Riemann surfaces. Hitchin baptized those fields as *Higgs fields* because in the context of physics and gauge theory, they describe similar particles to those described by the Higgs bosson. Later, Simpson used the name *Higgs bundle* for a holomorphic bundle together with a Higgs field. Today, Higgs bundles are the subject of research in several areas such as non-abelian Hodge theory, Langlands, mirror symmetry, integrable systems, quantum field theory (QFT), among others. The main purposes here are to introduce these objects, and to present a brief but complete construction of the moduli space of Higgs bundles.

Keywords: Higgs bundles; Hodge bundles; moduli spaces; stable triples; vector bundles.

Resumen

Considerando una superficie compacta de Riemann de género mayor o igual que dos, un fibrado de Higgs es un par compuesto por un fibrado holomorfo sobre la superficie de Riemann, junto con un campo vectorial auxiliar, llamado campo de Higgs. Esta teoría inició hace unos treinta años, con el trabajo de Hitchin, cuando él reduce las ecuaciones de autodualidad de dimensión cuatro a dimensión dos, y así, estudiar esas ecuaciones sobre superficies de Riemann. Hitchin bautizó esos campos como *campos de Higgs* pues en el contexto de la física y de la teoría de gauge, describen partículas similares a las descritas por el bozón de Higgs. Más tarde, Simpson usó el nombre fibrado de Higgs para un fibrado holomorfo junto con un campo de Higgs. Hoy, los fibrados de Higgs son objeto de investigación en varias áreas tales como la teoría de Hodge no abeliana, Langlands, simetría de espejo, sistemas integrables, teoría cuántica de campos (OFT), entre otros. Los propósitos principales aquí son introducir estos objetos y presentar una breve pero completa construcción del espacio móduli de los fibrados de Higgs y algunas de sus estratificaciones.

Palabras clave: fibrados de Higgs; fibrados de Hodge; espacios móduli; triples estables; fibrados vectoriales.

Mathematics Subject Classification: Primary 14H60, Secondaries 14D07, 55Q52.

1 Introduction

Nineteen years ago, the Clay Institute of Cambridge, Massachusets, presented seven millenium challenging problems. Yang-Mills and Mass Gap is one of those challenging unsolved problems. Newton's classical mechanics laws stand to planets and celestial bodies as Quantum laws stand to elementary particles. Sixty five years ago, C. N. Yang and R. L. Mills [18] introduced a remarkable framework to describe particles using structures that occur in geometry. Quantum Yang-Mills theory is nowadays the foundation of elementary particle physics theory and its predictions have been tested at many laboratories; nevertheless, its mathematical foundations are still a mystery. Yang-Mills theory depends on a quantum mechanical property, the mass gap: the quantum particles have positive masses, even though the classical waves travel at the speed of light. Establishing the existence of the Yang-Mills theory and a mass gap will require the introduction of fundamental new ideas both in physics and in mathematics. Thirty two years ago, Hitchin [9] reduced Yang-Mills self-duality equations from \mathbb{R}^4 to \mathbb{R}^2 imposing invariance translation in two directions, and considering an auxiliar vector field, so-called Higgs field. Hitchin's reduction of Yang-Mills self-duality equations in \mathbb{R}^2 have the important property of conformal invariance, which allows them to be defined on Riemann surfaces.

Let $\Sigma = \Sigma_g$ be a compact (closed and connected) Riemann surface of genus $g \ge 2$. Let $K = K_{\Sigma} = T^*\Sigma$ be the canonical line bundle over Σ (its cotangent bundle).

Remark 1. Algebraically, Σ_g is also a complete irreducible nonsingular algebraic curve over \mathbb{C} :

$$\dim_{\mathbb{C}}(\Sigma_q) = 1.$$

The paper is organized as follows: in Section 2 we recall some preliminary facts about differential geometry, specifically about smooth vector bundles and holomorphic vector bundles; in Section 3, we present the gauge group action over the set of connections and the induced action over the holomorphic structures; in Section 4, we define the moduli space of Higgs bundles, and we present the two principal Hitchin constructions for rank two: the differential geometry flavor, and the algebraic geometry flavor in 4.2; in 4.3 we present Simpsons contribution to higher rank; in Section 5, we recall some basic facts about stratifications of the moduli space of Higgs bundles: Shatz stratification in 5.1 and Białynicki-Birula stratification in 5.2; in Section 6, we present our most recent results, those related to stratifications published in [5], and those related to homotopy published in [20].

2 Preliminary definitions

We shall recall some basic definitions we will need, like bundles and some of their invariants such as rank, degree and slope. We also present the definition of stability.

Definition 1. For any smooth vector bundle $\mathcal{E} \to \Sigma$, we denote the rank of \mathcal{E} by $\operatorname{rk}(\mathcal{E}) = r$ and the degree of \mathcal{E} by $\operatorname{deg}(\mathcal{E}) = d$. Then, for any smooth complex bundle $\mathcal{E} \to \Sigma$ the slope is defined to be

$$\mu(\mathcal{E}) := \frac{\deg(\mathcal{E})}{\operatorname{rk}(\mathcal{E})} = \frac{d}{r}.$$
(1)

Definition 2. A smooth vector bundle $\mathcal{E} \to \Sigma$ is called semistable if $\mu(\mathcal{F}) \leq \mu(\mathcal{E})$ for any \mathcal{F} such that $0 \subsetneq \mathcal{F} \subseteq \mathcal{E}$. Similarly, a vector bundle $\mathcal{E} \to \Sigma$ is called stable if $\mu(\mathcal{F}) < \mu(\mathcal{E})$ for any nonzero proper subbundle $0 \subsetneq \mathcal{F} \subsetneq \mathcal{E}$. Finally, $\mathcal{E} \to \Sigma$ is called polystable if it is the direct sum of stable subbundles, all of the same slope.

Let $\mathcal{E}\to\Sigma$ be a complex smooth vector bundle with a hermitian metric on it.

Definition 3. A connection d_A on \mathcal{E} is a differential operator

$$d_A: \Omega^0(\Sigma, \mathcal{E}) \to \Omega^1(\Sigma, \mathcal{E}),$$

such that

$$d_A(fs) = df \otimes s + f d_A s,$$

for any function $f \in C^{\infty}(\Sigma)$ and any section $s \in \Omega^{0}(\Sigma, \mathcal{E})$ where $\Omega^{n}(\Sigma, \mathcal{E})$ is the set of smooth *n*-forms of Σ with values in \mathcal{E} . Locally:

$$d_A = d + A = d + Cdz + Bd\bar{z},$$

where A is a matrix of 1-forms: $A_{ij} \in \Omega^1(\Sigma, \mathcal{E})$, and B, C are matrix valued functions depending on the hermitian metric on \mathcal{E} .

Definition 4. When a connection d_A is compatible with the hermitian metric on \mathcal{E} ,

i.e.
$$d\langle s,t\rangle = \langle d_As,t\rangle + \langle s,d_At\rangle,$$

for the hermitian inner product $\langle \cdot, \cdot \rangle$ and for s, t any couple of sections of \mathcal{E} , d_A is a unitary connection. Denote $\mathcal{A}(\mathcal{E})$ as the space of unitary connections on \mathcal{E} , for a smooth bundle $\mathcal{E} \to \Sigma$.

Remark 2. Some authors call the matrix A as a connection and call $d_A = d + A$ as its correspoding covariant derivative. We abuse notation and will not distinguish between them.

Definition 5. *The fundamental invariant of a connection is its* curvature:

$$F_A := d_A^2 = d_A \circ d_A : \Omega^0(\Sigma, \mathcal{E}) \to \Omega^2(\Sigma, \mathcal{E}),$$

where we are extending d_A to n-forms in $\Omega^n(\Sigma, \mathcal{E})$ in the obvious way. Locally:

$$F_A = dA + A^2.$$

 F_A is $C^{\infty}(\Sigma, \mathcal{E})$ -linear and can be considered as a 2-form on Σ with values in $\operatorname{End}(\mathcal{E})$: $F_A \in \Omega^2(\Sigma, \operatorname{End}(\mathcal{E}))$, or locally as a matrix-valued 2-form.

Definition 6. If the curvature vanishes $F_A = 0$, we say that the connection d_A is flat. A flat connection gives a family of constant transition functions for \mathcal{E} , which in turn defines a representation of the fundamental group $\pi_1(\Sigma)$ into $GL_r(\mathbb{C})$, and the image is in U(r) if d_A is unitary. Besides, from Chern-Weil theory, if $F_A = 0$, then $\deg(\mathcal{E}) = 0$.

3 Gauge group action

The gauge theory arises first in the context of physics, specifically in general relativity and classical electromagnetism. Here, we present the mathematical formalism.

Definition 7. A gauge transformation is an automorphism of \mathcal{E} . Locally, a gauge transformation $g \in Aut(\mathcal{E})$ is a C^{∞} -function with values in $GL_r(\mathbb{C})$. A gauge transformation g is unitary if g preserves the hermitian inner product.

We denote by \mathcal{G} the group of unitary gauge transformations. This gauge group \mathcal{G} acts on $\mathcal{A}(\mathcal{E})$ by conjugation:

$$g \cdot d_A = g^{-1} d_A g$$
, $\forall g \in \mathcal{G} \text{ and for } d_A \in \mathcal{A}(\mathcal{E}).$

Remark 3. Note that conjugation by a unitary gauge transformation takes a unitary connection to a unitary connection. We denote by $\overline{\mathcal{G}}$ the quotient of \mathcal{G} by the central subgroup U(1), and by $\mathcal{G}^{\mathbb{C}}$ the complex gauge group. Besides, we denote by $B\mathcal{G}$ and by $B\overline{\mathcal{G}}$ the classifying spaces of \mathcal{G} and $\overline{\mathcal{G}}$ respectively. There is a homotopical equivalence: $\mathcal{G} \simeq \mathcal{G}^{\mathbb{C}}$.

Rev.Mate.Teor.Aplic. (ISSN print: 1409-2433; online: 2215-3373) Vol. 26(2): 197-214, Jul-Dec 2019

Definition 8. A holomorphic structure on \mathcal{E} is a differential operator:

 $\bar{\partial}_A: \Omega^0(\Sigma, \mathcal{E}) \to \Omega^{0,1}(\Sigma, \mathcal{E}),$

such that $\bar{\partial}_A$ satisfies Liebniz rule:

$$\bar{\partial}_A(fs) = \bar{\partial}f \otimes s + f\bar{\partial}_A s$$

and the integrability condition, which is precisely vanishing of the curvature

 $F_A = 0.$

Here, $\bar{\partial}f = \frac{\partial f}{\partial \bar{z}} d\bar{z}$, and $\Omega^{p,q}(\Sigma, \mathcal{E})$ is the space of smooth (p,q)-forms with values in \mathcal{E} . Locally:

$$\bar{\partial}_A = \bar{\partial} + A^{0,1} d\bar{z}$$

where $A^{0,1}$ is a matrix valued function. The reader may consult the details in [10, 11, 12].

Remark 4. Denote the space of holomorphic structures on \mathcal{E} by $\mathcal{A}^{0,1}(\mathcal{E})$, and consider the collection $\mathcal{A}^{0,1}(r,d) = \{\mathcal{A}^{0,1}(\mathcal{E}): \operatorname{rk}(\mathcal{E}) = r \text{ and } \operatorname{deg}(\mathcal{E}) = d\}$. Here, the subcollections

$$\begin{aligned} \mathcal{A}_{ss}^{0,1}(r,d) &= \{\mathcal{A}^{0,1}(\mathcal{E}) \colon \mathcal{E} \quad is \; semistable \quad \} \subseteq \mathcal{A}^{0,1}(r,d), \\ \mathcal{A}_{s}^{0,1}(r,d) &= \{\mathcal{A}^{0,1}(\mathcal{E}) \colon \mathcal{E} \quad is \; stable \quad \} \subseteq \mathcal{A}^{0,1}(r,d), \\ \mathcal{A}_{ps}^{0,1}(r,d) &= \{\mathcal{A}^{0,1}(\mathcal{E}) \colon \mathcal{E} \quad is \; polystable \quad \} \subseteq \mathcal{A}^{0,1}(r,d), \end{aligned}$$

will be of particular interest for us.

4 Moduli space of Higgs bundles

A central feature of Higgs bundles, is that they come in collections parametrized by the points of a quasi-projective variety: the Moduli Space of Higgs Bundles.

4.1 Moduli space of vector bundles

The starting point to classify these collections, is the Moduli Space of Vector bundles. Using Mumford's Geometric Invariant Theory¹ (GIT), first Narasimhan and Seshadri [14], and then Atiyah and Bott [1], build and charaterize this family of bundles by Morse theory and by their stability. Both classifications are equivalent.

¹For details on GIT, see Mumford, Fogarty and Kirwan [13].

Rev.Mate.Teor.Aplic. (ISSN print: 1409-2433; online: 2215-3373) Vol. 26(2): 197-214, Jul-Dec 2019

We use the one from stability here:

Definition 9. Define the moduli space of (polystable) vector bundles $\mathcal{E} \to \Sigma$ as the quotient

$$\mathcal{N}(r,d) = \mathcal{A}_{ps}^{0,1}(r,d) / \mathcal{G}^{\mathbb{C}}.$$

Respectively, define the moduli space of stable vector bundles as the quotient

$$\mathcal{N}_s(r,d) = \mathcal{A}_s^{0,1}(r,d)/\mathcal{G}^{\mathbb{C}} \subseteq \mathcal{N}(r,d).$$

Remark 5. The quotient $\mathcal{A}^{0,1}(r,d)/\mathcal{G}^{\mathbb{C}}$ is not Hausdorff so, we may lose a lot of interesting properties.

Narasimhan and Seshadri [14] charaterize this variety (see also Atiyah and Bott [1]), and conclude in their work that:

Theorem 1. [14] If GCD(r, d) = 1, then $\mathcal{A}_{ps}^{0,1} = \mathcal{A}_s^{0,1}$ and $\mathcal{N}(r, d) = \mathcal{N}_s(r, d)$ is a smooth complex projective variety of dimension

$$\dim_{\mathbb{C}} \left(\mathcal{N}(r,d) \right) = r^2(g-1) + 1. \quad \boxminus$$

4.2 Hitchin construction

Hitchin [9] works with the Yang-Mills self-duality equations (SDE)

$$\begin{cases} F_A + [\varphi, \varphi^*] = 0 \\ \bar{\partial}_A \varphi = 0, \end{cases}$$
(2)

where $\varphi \in \Omega^{1,0}(\Sigma, \operatorname{End}(\mathcal{E}))$ is a complex auxiliary field and F_A is the curvature of a connection d_A which is compatible with the holomorphic structure of the bundle $E = (\mathcal{E}, \overline{\partial}_A)$, and \mathcal{E} has rank $\operatorname{rk}(\mathcal{E}) = 2$ and degree $\operatorname{deg}(\mathcal{E}) = 1$. Hitchin calls φ Higgs field, because it shares a lot of the physical and gauge properties of those of the Higgs boson. Here, φ^* denotes the adjoint of φ with respect to the hermitian metric on E, and $[\cdot, \cdot]$ denotes the extension of the Lie bracket to Lie algebra-valued forms. For details, the reader may see Hitchin [9].

The set of solutions

$$\beta(\mathcal{E}) := \{ (\bar{\partial}_A, \varphi) | \text{ solution of } (2) \} \subseteq \mathcal{A}^{0,1}(\mathcal{E}) \times \Omega^{1,0}(\Sigma, \operatorname{End}(\mathcal{E}))$$

and the collection

$$\beta_{ps}(2,1) := \{\beta(\mathcal{E}) | \mathcal{E} \text{ polystable, } \operatorname{rk}(\mathcal{E}) = 2, \operatorname{deg}(\mathcal{E}) = 1\}$$

allow Hitchin to construct the Moduli space of solutions to SDE (2)

$$\mathcal{M}^{YM}(2,1) = \beta_{ps}(2,1)/\mathcal{G}^{\mathbb{C}},$$

and

$$\mathcal{M}_s^{YM}(2,1) = \beta_s(2,1)/\mathcal{G}^{\mathbb{C}} \subseteq \mathcal{M}^{YM}(2,1),$$

the moduli space of stable solutions to SDE (2).

Remark 6. Since GCD(2,1) = 1, then $A_{ps}^{0,1} = A_s^{0,1}$ and so

$$\mathcal{M}^{YM}(r,d) = \mathcal{M}^{YM}_s(r,d)$$

An alternative algebro-geometric construction is presented also in the work of Hitchin [9] [10]:

Definition 10. A Higgs bundle over Σ is a pair (E, φ) where $E \to \Sigma$ is a holomorphic vector bundle together with φ , an endomorphism of E twisted by $K = T^*(\Sigma) \to \Sigma$, the canonical line bundle of the surface $\Sigma: \varphi: E \to E \otimes K$. The field φ is what Hitchin calls Higgs field.

There is a condition of stability analogous to the one for vector bundles, but with reference just to subbundles preserved by the endomorphism φ :

Definition 11. A subbundle $F \subseteq E$ is said to be φ -invariant if $\varphi(F) \subseteq F \otimes K$. A Higgs bundle is said to be semistable [respectively, stable] if $\mu(F) \leq \mu(E)$ [resp., $\mu(F) < \mu(E)$] for any nonzero φ -invariant subbundle $F \subseteq E$ [resp., $F \subsetneq E$]. Finally, (E, φ) is called polystable if it is the direct sum of stable φ -invariant subbundles, all of the same slope.

With this notion of stability in mind, Hitchin [9] constructs the moduli space of Higgs bundles as the quotient

$$\mathcal{M}^{H}(2,1) = \{(E,\varphi) | E \text{ polystable } \} / \mathcal{G}^{\mathbb{C}}$$

and the subspace

$$\mathcal{M}^H_s(2,1) = \{(E,\varphi) | E \text{ stable } \} / \mathcal{G}^{\mathbb{C}} \subseteq \mathcal{M}^H(2,1),$$

of stable Higgs bundles.

Remark 7. Again, GCD(2,1) = 1 implies $\mathcal{M}^{H}(2,1) = \mathcal{M}^{H}_{s}(2,1)$.

Finally, Hitchin [9] concludes:

Theorem 2. [9] *There is a homeomorphism of topological spaces*

 $\mathcal{M}^H(2,1) \cong \mathcal{M}^{YM}(2,1).$

Hitchin [9] computes the real dimension of the moduli space of stable rank two pairs (E, φ) , $\mathcal{M}(2, 1)$ for brief:

Theorem 3. [9, Th. 5.8.] Let $\Sigma = \Sigma_g$ be a compact Riemann surface of genus g > 1. The moduli space $\mathcal{M}(2,1)$ of all stable pairs (E,φ) , where $E \to \Sigma$ is a rank two holomorphic vector bundle of degree one, and φ is a trace free holomorphic section of $\operatorname{End}(E) \otimes K$, is a smooth real manifold of dimension

$$\dim_{\mathbb{R}} \left(\mathcal{M}(2,1) \right) = 12(g-1).$$

Corollary 1. The space $\mathcal{M}(2,1)$ is a quasi-projective variety of complex dimension

$$\dim_{\mathbb{C}} \left(\mathcal{M}(2,1) \right) = 3(2g-2).$$

4.3 General rank

Nitsure [15] constructs the moduli space of Higgs bundles of general rank r and degree d using GIT, and computes its dimension:

Theorem 4. [15] The space $\mathcal{M}(r, d)$ is a quasi-projective variety of complex dimension

$$\dim_{\mathbb{C}} \left(\mathcal{M}(r,d) \right) = (r^2 - 1)(2g - 2).$$

Remark 8. Note that the result of Nitsure [15] coincides with the result of Hitchin [9] for rank two Higgs bundles.

Simpson [17] calls the pair (E, φ) as *Higgs bundle*. His work contributes generalizing Higgs bundles to higher dimensions and proving an analogous proposition to Theorem 3 for general rank, with the same notion of stability in mind, considering the moduli space of Higgs bundles as the quotient

$$\mathcal{M}^{H}(r,d) = \{(E,\varphi) | E \text{ polystable } \}/\mathcal{G}^{\mathbb{C}}$$

and the subspace

$$\mathcal{M}^H_s(r,d) = \{(E,\varphi) | E \text{ stable } \} / \mathcal{G}^{\mathbb{C}} \subseteq \mathcal{M}^H(r,d),$$

of stable Higgs bundles.

Rev.Mate.Teor.Aplic. (ISSN print: 1409-2433; online: 2215-3373) Vol. 26(2): 197-214, Jul-Dec 2019

Remark 9. Once again, GCD(r, d) = 1 implies $\mathcal{M}^H(r, d) = \mathcal{M}^H_s(r, d)$. See Simpson [17] for details.

Theorem 5. [17, Prop. 1.5] *There is a homeomorphism of topological spaces*

$$\mathcal{M}^H(r,d) \cong \mathcal{M}^{YM}(r,d).$$

5 Stratifications

5.1 Harder-Narasimhan filtrations and the Shatz stratification

The Harder–Narasimhan filtration of a vector bundle was introduced in [7] and studied systematically by Shatz [16]. It plays an important role in the work of Atiyah and Bott [1]. We refer the reader to these references for details on what follows.

Let E be a holomorphic vector bundle on X. A Harder-Narasimhan Filtration of E, is a filtration of the form

$$HNF(E): E = E_s \supset E_{s-1} \supset \dots \supset E_1 \supset E_0 = 0, \tag{3}$$

which satisfies the following two properties:

- (i) $\mu(E_{j+1}/E_j) < \mu(E_j/E_{j-1})$ for $1 \le j \le s-1$.
- (ii) E_j/E_{j-1} is semistable for $1 \leq j \leq s$.

For brevity, when we have a filtration $E = E_s \supset E_{s-1} \supset \cdots \supset E_1 \supset E_0 = 0$ we shall sometimes write $\overline{E}_j = E_j/E_{j-1}$ for the subquotients. The associated graded vector bundle is

$$\operatorname{Gr}(E) = \bigoplus_{j=1}^{s} E_j / E_{j-1} = \bigoplus_{j=1}^{s} \overline{E}_j.$$

Remark 10. Property (i) $\mu(\bar{E}_{j+1}) < \mu(\bar{E}_j)$ for $1 \le j \le s-1$ is equivalent to $\mu(E_{j+1}) < \mu(E_j)$ for $1 \le j \le s-1$, which is intuitively clear if we take a view to the Harder-Narasimhan Polygon (for more details, see Shatz [16, Prop. 5]), Figure 1.

Figure 1: On the left, the Harder-Narasimhan Polygon, where the black points represent the pairs (r_i, d_i) for E_i , and the blue line segments represent segments with slope $\mu(V_i) = \mu(E_i/E_{i-1})$. On the right, the red-dashed line segments represent segments with slope $\mu(E_i)$.

Any vector bundle E has a unique Harder–Narasimhan filtration. The *Harder–Narasimhan polygon* is the polygon in the first quadrant of the (r, d)-plane with vertices $(\operatorname{rk}(E_j), \operatorname{deg}(E_j))$ for $j = 0, \ldots, s$. The slope of the line joining $(\operatorname{rk}(E_{j-1}), \operatorname{deg}(E_{j-1}))$ and $(\operatorname{rk}(E_j), \operatorname{deg}(E_j))$ is $\mu(\overline{E}_j)$. Condition (i) above says that the Harder–Narasimhan polygon is convex. Clearly this is equivalent to saying that $\mu(E_j) < \mu(E_{j-1})$ for $j = 2, \ldots, s$.

The Harder–Narasimhan type of E is the vector in \mathbb{Q}^r :

$$HNT(E) = \overrightarrow{\mu} = \left(\mu(\overline{E}_1), \dots, \mu(\overline{E}_1), \dots, \mu(\overline{E}_s), \dots, \mu(\overline{E}_s)\right)$$

where the slope of each \bar{E}_i is repeated $rk(\bar{E}_i)$ times.

As a consequence of Shatz [16, Prop. 10 & 11], there is a finite stratification of $\mathcal{M}(r, d)$ by the Harder–Narasimhan type of the underlying vector bundle E of a Higgs bundle (E, φ) :

$$\mathcal{M}(r,d) = \bigcup_{\mu} U'_{\mu}$$

where $U'_{\mu} \subseteq \mathcal{M}(r, d)$ is the subspace of Higgs bundles (E, φ) whose underlying vector bundle E has Harder–Narasimhan type μ . This stratification is known as the *Shatz stratification*. Note that there is an open dense stratum corresponding to Higgs bundles (E, φ) for which the underlying vector bundle E is itself stable. Since $\varphi \in H^0(\text{End}(E) \otimes K) \cong H^1(\text{End}(E))^*$ (by Serre duality) such a Higgs bundle represents a point in the cotangent bundle of the moduli space of stable bundles $\mathcal{N}(r, d)$. In other words,

$$U'_{(d/r,\ldots,d/r)} = T^* \mathcal{N}(r,d) \subseteq \mathcal{M}(r,d).$$

Rev.Mate.Teor.Aplic. (ISSN print: 1409-2433; online: 2215-3373) Vol. 26(2): 197-214, Jul-Dec 2019

5.2 The C*-action and the Białynicki-Birula stratification

We review some standard facts about the \mathbb{C}^* -action on $\mathcal{M}(r, d)$. For more details see, e.g., Simpson [17].

The holomorphic action of the multiplicative group \mathbb{C}^* on $\mathcal{M}(r, d)$ is defined by multiplication $z \cdot (E, \varphi) \mapsto (E, z \cdot \varphi)$. The limit $(E_0, \varphi_0) = \lim_{z \to 0} z \cdot (E, \varphi)$ exists for all $(E, \varphi) \in \mathcal{M}(r, d)$. Moreover, this limit is fixed by the \mathbb{C}^* -action. A Higgs bundle (E, φ) is a fixed point of the \mathbb{C}^* -action if and only if it is a *Hodge* bundle: there is a decomposition $E = \bigoplus_{j=1}^p E_j$ with respect to which the Higgs field φ has weight one: $\varphi \colon E_j \to E_{j+1} \otimes K$. The type of the Hodge bundle (E, φ) is $(\operatorname{rk}(E_1), \ldots, \operatorname{rk}(E_p))$. Let $\{F_\lambda\}$ be the irreducible components of the fixed point locus of \mathbb{C}^* on $\mathcal{M}(r, d)$. Consider the upper flow sets

$$U_{\lambda}^{+} := \{ (E, \varphi) \in \mathcal{M} \colon \lim_{z \to 0} z \cdot (E, \varphi) \in F_{\lambda} \}.$$

Then we have the *Białynicki-Birula stratification* (cf. [2]) of $\mathcal{M}(r, d)$:

$$\mathcal{M} = \bigcup_{\lambda} U_{\lambda}^+.$$

6 Recent results

6.1 Stratifications

Motivated by the results of Hausel [8], in terms of stratifications of the moduli space of rank two Higgs bundles, we have tried to improve the results of Hausel to rank three. So far, here are the main results. Recall that here, we only announce the results, no formal proofs are given. The reader can find the detailed proofs in [5]. First, we will present the bounds on Harder–Narasimhan types for rank three Higgs bundles. Let (E, φ) be a rank 3 Higgs bundle. Let (μ_1, μ_2, μ_3) be the Harder–Narasimhan type of E, so that $\mu_1 \ge \mu_2 \ge \mu_3$ and $\mu_1 + \mu_2 + \mu_3 = 3\mu$, where $\mu = \mu(E)$. We can write the Harder–Narasimhan filtration of the vector bundle E as follows:

$$\operatorname{HNF}(E): 0 = E_0 \subseteq E_1 \subseteq E_2 \subseteq E_3 = E_4$$

where we have made the convention that $E_i = E_j$ if $\mu_i = \mu_j$. Thus, for example, if $\mu_1 = \mu_2 > \mu_3$ then the Harder–Narasimhan filtration is

$$\operatorname{HNF}(E): 0 = E_0 \subseteq E_1 = E_2 \subseteq E_3 = E$$

Rev.Mate.Teor.Aplic. (ISSN print: 1409-2433; online: 2215-3373) Vol. 26(2): 197-214, Jul-Dec 2019

Remark 11. Let (E, φ) be a stable Higgs bundle such that E is an unstable vector bundle of $HNT(E) = (\mu_1, \mu_2, \mu_3)$. Then $E_1 \subseteq E_2$ is destabilizing and hence, by stability of (E, φ) , we have $\varphi_{21} \neq 0$ where $\varphi = \begin{pmatrix} \varphi_{21} & 0 & 0 \\ \varphi_{21} & 0 & 0 \\ 0 & \varphi_{32} & 0 \end{pmatrix}$. Similarly $E_2 \subseteq E$ is destabilizing and so $\varphi_{32} \neq 0$ (unless $\mu_2 = \mu_3 \iff E_2 = E$).

After analyzing the image and the kernel of φ , we get the following bounds:

Proposition 1. Let (E, φ) be a semistable rank 3 Higgs bundle of $HNT(E) = (\mu_1, \mu_2, \mu_3)$. Then

$$0 \leqslant \mu_1 - \mu_2 \leqslant 2g - 2,\tag{4}$$

$$0 \leqslant \mu_2 - \mu_3 \leqslant 2g - 2. \tag{5}$$

The purpose now will be to analyze the \mathbb{C}^* -action limit as $z \to 0$ of $z \cdot (E, \varphi)$ as a function of HNT(E). Let start by trivial filtrations. Let (E, φ) be a stable Higgs bundle. When the underlying vector bundle E is itself stable, clearly $\lim_{z\to 0} z \cdot (E, \varphi) = (E, 0)$. Hence we have the following result, valid for any rank.

Proposition 2. Let $(E, \varphi) \in \mathcal{M}(r, d)$. Then $\lim_{z \to 0} z \cdot (E, \varphi) = (E, 0)$ if and only if E is stable.

Proof. It only remains to observe that if $(E, 0) = \lim_{z \to 0} z \cdot (E, \varphi)$ is a stable Higgs bundle then E is a stable vector bundle.

Now, let see non-trivial Harder–Narasimhan filtrations. Let consider rank 3 stable Higgs bundles (E, φ) and assume that (3, d) = 1.

Theorem 6. Let $(E, \varphi) \in \mathcal{M}(3, d)$ be such that E is an unstable vector bundle of slope μ and $\text{HNT}(E) = (\mu_1, \mu_2, \mu_3)$. Then the limit $(E_0, \varphi_0) = \lim_{z \to 0} (E, z \cdot \varphi)$ is given as follows.

- (1) Assume that $\mu_2 < \mu$. Then $\mu_1 > \mu_2 \ge \mu_3$ and one of the following alternatives holds.
 - (1.1) The slope of $I = \varphi_{21}(E_1) \otimes K^{-1}$ satisfies $\mu_1 (2g 2) \leq \mu(I) < -\frac{1}{3}\mu_1 + \frac{2}{3}\mu_2 + \frac{2}{3}\mu_3$ and (E_0, φ_0) is the following Hodge bundle of type (1, 2):

$$(E_0,\varphi_0) = \left(E_1 \oplus E/E_1, \begin{pmatrix} 0 & 0\\ \varphi_{21} & 0 \end{pmatrix}\right).$$

The associated graded vector bundle is $Gr(E_0) = Gr(E)$.

(1.2) The slope of $I = \varphi_{21}(E_1) \otimes K^{-1}$ satisfies $-\frac{1}{3}\mu_1 + \frac{2}{3}\mu_2 + \frac{2}{3}\mu_3 < \mu(I) \leq \mu_3$ and (E_0, φ_0) is the following Hodge bundle of type (1, 1, 1):

$$(E_0,\varphi_0) = \left(E_1 \oplus I \oplus (E/E_1)/I, \begin{pmatrix} 0 & 0 & 0\\ \varphi_{21} & 0 & 0\\ 0 & \varphi_{32} & 0 \end{pmatrix}\right),$$

where φ_{21} and φ_{32} are induced from φ . The associated graded vector bundle is $\operatorname{Gr}(E_0) = E_1 \oplus (E/E_1)/I \oplus I$ and $\operatorname{HNT}(E_0) = (\mu_1, \mu_2 + \mu_3 - \mu(I), \mu(I)).$

(1.3) The slope of $I = \varphi_{21}(E_1) \otimes K^{-1}$ satisfies $\mu(I) = \mu_2$ and the strict inequality $\mu_3 < \mu_2$ holds. Moreover, the line bundle $I = E_2/E_1$ and (E_0, φ_0) is the following Hodge bundle of type (1, 1, 1):

$$(E_0,\varphi_0) = \left(E_1 \oplus E_2 / E_1 \oplus E / E_2, \begin{pmatrix} 0 & 0 & 0 \\ \varphi_{21} & 0 & 0 \\ 0 & \varphi_{32} & 0 \end{pmatrix} \right)$$

where φ_{32} is induced from φ . The associated graded vector bundle is $\operatorname{Gr}(E_0) = \operatorname{Gr}(E)$.

- (2) Suppose that $\mu_2 > \mu$. Then $\mu_1 \ge \mu_2 > \mu_3$ and one of the following alternatives holds.
 - (2.1) The slope of $N = \ker(\varphi_{32})$ satisfies $\mu_1 + \mu_2 \mu_3 (2g 2) \leq \mu(N) < \mu$ and (E_0, φ_0) is the following Hodge bundle of type (2, 1):

$$(E_0,\varphi_0) = \left(E_2 \oplus E/E_2, \begin{pmatrix} 0 & 0\\ \varphi_{32} & 0 \end{pmatrix}\right).$$

The associated graded vector bundle is $Gr(E_0) = Gr(E)$.

(2.2) The slope of $N = \ker(\varphi_{32})$ satisfies $\mu < \mu(N) \leq \mu_2$ and (E_0, φ_0) is the following Hodge bundle of type (1, 1, 1):

$$(E_0,\varphi_0) = \left(N \oplus E_2/N \oplus E/E_2, \begin{pmatrix} 0 & 0 & 0\\ \varphi_{21} & 0 & 0\\ 0 & \varphi_{32} & 0 \end{pmatrix}\right),$$

where φ_{21} and φ_{32} are induced from φ . The associated graded vector bundle is $\operatorname{Gr}(E_0) = E_2/N \oplus N \oplus E/E_2$ and $\operatorname{HNT}(E_0) = (\mu_1 + \mu_2 - \mu(N), \mu(N), \mu_3)$.

(2.3) The slope of $N = \ker(\varphi_{32})$ satisfies $\mu(N) = \mu_1$ and the strict inequality $\mu_1 > \mu_2$ holds. Moreover the line bundle $N = E_1$ and (E_0, φ_0) is the following Hodge bundle of type (1, 1, 1):

$$(E_0,\varphi_0) = \left(E_1 \oplus E_2 / E_1 \oplus E / E_2, \begin{pmatrix} 0 & 0 & 0 \\ \varphi_{21} & 0 & 0 \\ 0 & \varphi_{32} & 0 \end{pmatrix} \right).$$

where φ_{21} and φ_{32} are induced from φ . The associated graded vector bundle is $\operatorname{Gr}(E_0) = \operatorname{Gr}(E)$.

Rev.Mate.Teor.Aplic. (ISSN print: 1409-2433; online: 2215-3373) Vol. 26(2): 197-214, Jul-Dec 2019

Remark 12. Strictly speaking, we should use the saturated bundle of the sheaf $I = \varphi_{21}(E_1) \otimes K^{-1}$ as in [5]. We abuse of notation here.

Corollary 2. Let $(E, \varphi) \in \mathcal{M}(3, d)$ be such that E is an unstable vector bundle of slope μ and $HNT(E) = (\mu_1, \mu_2, \mu_3)$. Assume that $\mu_1 - \mu_3 > 2g - 2$. Then the limit $(E_0, \varphi_0) = \lim_{z \to 0} (E, z \cdot \varphi)$ is given by (1.3) of Theorem 6 if $\mu_2 < \mu$, and by (2.3) of Theorem 6 if $\mu_2 > \mu$.

Corollary 3. Let $(E_0 = L_1 \oplus L_2 \oplus L_3, \varphi_0 = \begin{pmatrix} 0 & 0 & 0 \\ \varphi_{21} & 0 & 0 \\ 0 & \varphi_{32} & 0 \end{pmatrix})$ be a Hodge bundle of type (1, 1, 1) with $\mu(L_1) - \mu(L_3) > 2g - 2$. Then $\mu(L_1) > \mu(L_2) > \mu(L_3)$ and any (E, φ) such that $\lim_{z \to 0} (E, z \cdot \varphi) = (E_0, \varphi_0)$ satisfies $\operatorname{Gr}(E) = \operatorname{Gr}(E_0)$.

Proof. Since $\varphi_{21} \neq 0$, we have $\mu(L_2) + 2g - 2 \ge \mu(L_1)$. This, together with $\mu(L_1) - \mu(L_3) > 2g - 2$ implies that $\mu(L_2) > \mu(L_3)$. Since in Cases (1.2) and (2.2) of Theorem 6 one has $\mu(L_2) \le \mu(L_3)$, it follows that the limit $(E_0, \varphi_=)$ must arise either from Case (1.3) or from Case (2.3). The conclusion follows since in these cases $\operatorname{Gr}(E) = \operatorname{Gr}(E_0)$.

The two previous corollaries lead to an identification between Shatz strata and Białynicki-Birula strata in some cases. Recall that the set $U^+_{(l_1,l_2,l_3)}$ denotes the Białynicki-Birula stratum of Higgs bundles whose limits lie in $F_{(l_1,l_2,l_3)}$ and that $U'_{(l_1,l_2,l_3)}$ denotes the Shatz stratum of Higgs bundles whose Harder– Narasimhan type is (l_1, l_2, l_3) .

Theorem 7. Let (l_1, l_2, l_3) be such that $l_1 - l_3 > 2g - 2$. Then the corresponding Shatz and Białynicki-Birula strata in $\mathcal{M}(3, d)$ coincide:

$$U'_{(l_1,l_2,l_3)} = U^+_{(l_1,l_2,l_3)}.$$

6.2 Homotopy

If we consider a fixed point $p \in X$ as a divisor $p \in \text{Sym}^1(X) = X$, and L_p the line bundle that corresponds to that divisor p, we get a complex of the form

$$E \xrightarrow{\varphi^k} E \otimes K \otimes L_p^{\otimes k},$$

where $\varphi^k \in H^0(X, \operatorname{End}(E) \otimes K \otimes L_p^{\otimes k})$ is a Higgs field with poles of order k. So, we call such a complex as a k-Higgs bundle and φ^k as its k-Higgs field. As well as for a Higgs bundle, a k-Higgs bundle (E, φ^k) is stable (respectively semistable) if the slope of any φ^k -invariant subbundle of E is strictly less (respectively less or equal) than the slope of $E : \mu(E)$. Finally, (E, φ^k) is called

Rev.Mate.Teor.Aplic. (ISSN print: 1409-2433; online: 2215-3373) Vol. 26(2): 197-214, Jul-Dec 2019

polystable if E is the direct sum of stable φ^k -invariant subbundles, all of the same slope. Motivated by the results of Bradlow, García-Prada and Gothen [4], and once again by the work of Hausel [8], in terms of the homotopy groups of the moduli space of Higgs bundles and k-Higgs bundles respectively, we have tried to improve the result of Hausel to higher rank. So far, here is one of the main results. Recall that here, we only announce the result, no proof is given. The reader can find the full detailed proof in [20].

Theorem 8. [20, Thm. 1.1] Suppose the rank is either r = 2 or r = 3, and GCD(r, d) = 1. Then, for all n exists k_0 , depending on n, such that

$$\pi_j\left(\mathcal{M}^k_{\Lambda}(r,d)\right) \xrightarrow{\cong} \pi_j\left(\mathcal{M}^\infty_{\Lambda}(r,d)\right),$$

for all $k \ge k_0$ and for all $j \le n-1$.

6.3 Further research

We are currently working on interesting results related with the homotopy of the moduli space of Higgs bundles, in terms of stratifications in the nilpotent cone [6], and in terms of Morse Theory and Variations of Hodge Structures [21, 20]. We encourage the reader to explore those results in the references above mentioned.

Acknowledgements

We thank Peter B. Gothen for introducing us to the beautiful subject of Higgs bundles. We thank the referees for their comments and suggestions. We thank organizers of XXI-SIMMAC-2018 for the opportunity of share our work with the scientific community. Financial support from Vicerrectoría de Investigación, Universidad de Costa Rica, is acknowledged.

Research supported by Universidad de Costa Rica through Escuela de Matemática and through CIMM (Centro de Investigaciones Matemáticas y Metamatemáticas), Project 820-B8-224. This work is partly based on the Ph.D. Project [19] called "Homotopy Groups of the Moduli Space of Higgs Bundles", supported by FEDER through Programa Operacional Factores de Competitividade-COMPETE, and also supported by FCT (Fundação para a Ciência e a Tecnologia) through the projects PTDC/MAT-GEO/0675/2012 and PEst-C/MAT/UI0144/2013 with grant reference SFRH/BD/51174/2010.
